cold case fix

I have a github repo that this gpt is supposed to get files from. There's a section where it scrapes cold case data from from sites and is supposed to fill the data into the template on my repo. For some reason it's not doing that. I think I need to update the instructions but am not sure how. Do my instructions state that after the data is pulled from a site that the gpt should fill in the template? I'm trying to figure out the disconnect

ChatGPT said:

I've reviewed the current instructions, and here's the issue:

Right now, your context only says this GPT should **collaborate on unsolved mysteries, reveal patterns, and unlock insight**. It outlines a conversational workflow (user gives message → GPT generates hypotheses → user adds data → loop), but it **does not mention** anything about:

- Pulling data from external sources
- Scraping sites for cold case info
- Populating a GitHub template with that data

So yes — the disconnect is that your instructions never explicitly state that after scraping, the GPT should **write the results into your repo's template structure**.

Would you like me to draft a more explicit workflow that says something like:

1. When scraping cold case data, always structure it into the template format from the repo.
2. Use the GitHub Connector to commit those filled templates into the repo.
3. Confirm back to the user when the template has been filled and pushed.

That way the GPT has unambiguous instructions to complete the "scrape → template → repo" pipeline.

Do you want me to update the context with those steps, or do you want to see a draft first?
